In industrial settings, contaminated water is often used for a variety of purposes, such as cooling water in a power plant or other industrial facility. In order to ensure that the use of contaminated water does not lead to adverse environmental consequences, the contaminated water is treated. Typically, the water is treated by passing it through a process that removes undesirable components. For example, the contaminated water may be treated to remove contaminants and impurities such as oil, sediment, carbon, and iron. The contaminants and impurities may then be removed from the water. Alternatively, the contaminated water may be treated to remove contaminants and impurities such as sulfur and chlorine. In either case, the water is usually passed through a tank or other vessel and a substance such as activated carbon is added to the water to absorb contaminants or impurities in the water. The treatment of contaminated water in a large facility typically involves the use of a distributed network of water purification devices. This may require hundreds, thousands or even millions of gallons of water to be treated at any one time. Consequently, a1d647c40b
