Metabolic profiling of human macrophages induced by soluble lipids from *Candida utilis* CBS 6123 and screening for anti-candidal properties of bioactive compounds. The utilization of lipids from microorganisms is a new strategy for the development of antimicrobial agents. A data set of metabolites produced by human macrophages induced by soluble lipids from *Candida utilis* CBS 6123 (M) and one set of primary and secondary metabolites from *C. utilis* CBS 6123 (D) were generated. Multivariate analyses were performed to compare the metabolite profiles between M and D. Supernatants of M stimulated with lipids from D showed increased levels of fatty acids, sterols and cell wall components. Other metabolites were decreased, including amino acids, purines and nucleosides. The result indicated that the metabolism of D was influenced by M. Further, 2-(2-hydroxy-1-phenylbutanoyl)-1-phenylacetyl-sn-glycero-3-phosphocholine (WPBP3) was found to be the major compound in the lipids extracted from D. WPBP3 has been shown to have potent anti-bacterial activity against *S. aureus*, but little is known about its anti-fungal activity. WPBP3 treatment did not affect the viability of either *C. utilis* or two other yeasts. We conclude that WPBP3 may have potential in controlling candidal growth. The invention relates to the field of the making and use of microcapsules. More particularly the invention is concerned with an improved process for encapsulating materials in microcapsules. Various processes have been devised for encapsulating substances in microcapsules for use in numerous applications. Usually, such processes involve a core component and a shell component wherein the shell has been derived from a polymer which is dissolved in a solvent and polymerized to form the shell. The encapsulating polymer may be dissolved in a solvent and then mixed with the substance to be encapsulated, in another solvent. The polymer which has been dissolved in the solvent is then polymerized by any number of known techniques to form the shell around the contents of the capsules. One such process which has been used extensively is the interfacial polymerization process. This process generally involves the use of two immiscible solvents, one containing the polymer
